User

Yes

Gemini

Could you please provide more details about what you mean by "Yes"? I need more information to understand your request.

User

So basically what we call weekly swing that stock goes up 5-8 percent and back . This is a accumulation period nothing else

Gemini

You are looking to analyze how these 5-8% weekly price swings characterize an accumulation phase and how to systematically identify this pattern, correct?

User

Yes

Gemini

Characterizing the 5-8% Weekly Swing

In an accumulation phase, these 5-8% swings represent **Institutional Absorption**. Large players cannot enter a position all at once without spiking the price; instead, they buy into "pockets" of liquidity, allowing the price to drift back down to find more sellers before repeating the process.

The Mechanics of the Swing

- **The Ceiling:** Professional sellers or profit-takers at the 5-8% mark create temporary resistance.
- **The Floor:** Strong hands buy the dip, preventing the stock from making new lows.
- **The Result:** A horizontal or slightly upward-sloping channel where the stock "coils."

Systematic Identification Indicators

To differentiate true accumulation from a stock that is simply "stuck," look for these specific signals:

Metric	Accumulation Characteristic
Volume	Expands on the 5-8% up-move; significantly dries up (lower than average) on the pullback.
Price Action	The "Low" of each swing is often slightly higher than the previous one (Higher Lows).
Volatility (ATR)	The daily range starts to shrink even while the weekly swing remains consistent.
VWAP	Price consistently tests and holds the **Anchored VWAP** from the start of the base.

Export to Sheets

Technical Filter Criteria

For a systematic scanner (e.g., in Kotlin or Python), you can define this accumulation period using the following logic:

- **Tightness Constraint:** The distance between the 20-day High and 20-day Low is less than 15%.
- **Volume Ratio:** Average volume on "Up" days is > 1.5x the average volume on "Down" days within the range.

- **RSI Support:** During the 5-8% pullbacks, the RSI (14) does not drop below 40, signaling that the trend remains bullishly neutral.
- **Moving Average Convergence:** The 10, 20, and 50-day Moving Averages begin to flatten and converge, indicating the "coil" is tightening.

The "Spring" Signal

The accumulation period typically ends with a **Shakeout** (a brief drop below the range to hit stop-losses) followed immediately by a high-volume breakout above the 8% resistance line. This transition marks the move from Phase A/B to Phase D in the Wyckoff framework, signaling the start of the **Markup** phase.

User

I see three stategy Mean reversion Momentum Volume weight average.
How big player use something else or hybrid of these

Gemini

Big players (Institutions, Hedge Funds, FIIs) rarely use these strategies in isolation. Instead, they operate through **Execution Algorithms** and **Regime-Adaptive Frameworks** that blend these three styles to hide their footprint.

1. The Hybrid Approach: Regime Switching

Institutions use "Adaptive Algorithms" that switch between Mean Reversion and Momentum based on the **Market Regime**.

Market State	Strategy Employed	Logic
Sideways (Accumulation)	**Mean Reversion**	They buy the "lows" of the 5-8% swing and stop buying at the "highs" to prevent the price from breaking out prematurely.
Trend (Markup Phase)	**Momentum**	Once the "coil" is tight, they switch to aggressive buying, often triggering retail "breakout" signals to move price quickly.
Overextended	**Hybrid**	They may use mean reversion to "trim" positions (sell) when a stock deviates too far from its VWAP, even in a strong uptrend.

Export to Sheets

2. The "Something Else": Execution Algorithms

A "Big Player" cannot simply hit the "Buy" button for 1,000,000 shares. They use specific execution logic to fill orders during those weekly swings:

POV (Percentage of Volume)

This is the most common "Stealth" tool. The algorithm is programmed to participate in only **5-10% of the total market volume** at any given moment.

- **If volume dries up:** The algo stops buying.
- **If volume spikes:** The algo buys more.
- **Result:** It keeps the stock in that "accumulation" range without alerting retail scanners.

Implementation Shortfall (IS)

This is a sophisticated hybrid. It calculates the trade-off between:

1. **Market Impact:** Buying too fast and pushing the price up.
2. **Opportunity Cost:** Buying too slow and missing the move. The algorithm dynamically adjusts between being a **passive buyer** (mean reversion style) and an **aggressive seeker** (momentum style).

---

3. Stealth Accumulation Techniques

Beyond your listed strategies, big players use "Dark" and "Hidden" methods:

- **Iceberg Orders:** Only a fraction of the total order is visible in the Level 2 data. When 100 shares are bought, another 100 instantly appear at the same price. This creates the "Floor" you see in accumulation.
- **Dark Pools:** Large blocks are traded off-exchange. You see the volume hit the "Tape" (Time & Sales) later, but it doesn't immediately move the public order book.
- **Liquidity Hunting (The "Spring"):** Before a big move, they may sell a small amount to push the price below a known support level. This triggers retail stop-losses (Mean Reversion traders exiting), providing the "big player" with the massive liquidity they need to buy their full position at a discount.

---

4. How They Use VWAP Differently

For you, VWAP is an indicator. For an Institutional Desk, **VWAP is a Performance Benchmark.**

+1

- A fund manager is judged by whether they bought **below** the day's VWAP.
- Their algorithms are strictly programmed to "buy into" pullbacks toward the VWAP (Mean Reversion) to ensure their average entry price is better than the market average. This is why you often see stocks "bounce" perfectly off the VWAP line during an accumulation phase.

In essence, they use **Mean Reversion to enter** (Accumulation), **VWAP to benchmark** (Execution), and **Momentum to exit** or drive the final markup.

User

Can you tell me 2 company strong company whose stock goes goes by 40-50 percent and then pull up to same high again . I want to study then first then I will come back with more questions

Gemini

Are you looking for companies that have recently completed a massive rally (40-50%) and are now consolidating in a range near their previous highs to study their accumulation patterns, correct?

User

Yes in india market

Gemini

As of mid-April 2026, the Indian market provides two standout examples that perfectly mirror the "40-50% rally followed by high-level accumulation" pattern you described. These companies are not just technical setups but "Pick and Shovel" plays for the AI and infrastructure themes you follow.

1. Bharat Electronics Limited (BEL)

BEL is a prime example of institutional accumulation following a massive structural rally.

- **The Rally:** Between early 2025 and early 2026, the stock moved from approximately **₹280 to its high of ₹473**, a gain of roughly **68%**.
- **The Accumulation:** Since hitting that high in early 2026, the stock has entered a wide consolidation zone. As of today (April 15, 2026), it is trading near **₹442**.
- **Study Points:** * Notice how the stock dropped from ₹473 to ₹397 (a healthy correction) and is now **pulling up** to test the ₹470 resistance again.
  - This "re-test" of the previous high after a 15-20% dip is the classic accumulation phase where weak hands are shaken out, and institutions re-load before the next "Markup" phase.

---

2. Cummins India (CUMMINSIND)

This stock is a critical infrastructure play (power generation for data centers) and has shown extreme price "tightness" near its all-time highs.

- **The Rally:** The stock saw a vertical run from its 52-week low of **₹2,706 to a high of ₹5,154**, nearly doubling in value (**~90% rally**).
- **The Accumulation:** After hitting the ₹5,154 peak on April 10, 2026, it saw a sharp 2-3% dip toward ₹4,980. However, it is already **pulling back up to the ₹5,100 level** within days.
- **Study Points:** * Observe the **Volatility Contraction**. The weekly swings are becoming smaller (tightening) as it nears the ₹5,154 resistance.
  - Check the volume on the current "pull up" toward ₹5,100; if it is lower than the initial rally volume, it confirms the "Coiling" effect we discussed earlier.

Comparison for Your Study

Feature	Bharat Electronics (BEL)	Cummins India (CUMMINSIND)
Current Pattern	Large Base (Wide Accumulation)	Tight Flag (High-Level Coil)
Sector Context	Defense/Pick & Shovel Electronics	Energy/AI Data Center Infrastructure

Feature	Bharat Electronics (BEL)	Cummins India (CUMMINSIND)
Price Action	Re-testing high after a deep dip	Hovering 1-2% below All-Time High

Export to Sheets

These two stocks allow you to study two different "flavors" of accumulation: BEL shows a **longer, deeper base**, while Cummins shows **extreme price strength** with almost no deep pullback.

Which of these two price behaviors (the deep base or the tight coil) aligns more with the "Weekly Swing" logic you are observing?

User

There are two strategies which come to my mind. I'm a retail trader. My capital is currently between 2 and 4 lakhs only, so I have two options, two strategies to implement: 1. Find where the accumulation is happening, and here I will do the 5% swing buying and selling at 5%. I don't care about accumulation; once the accumulation is happening, the stock will move further. 2. The momentum strategy, where we are saying that, "Okay, volume is high, the stock has broken out; then we'll definitely move another 5% and invest in that and churn out 5% or even higher."

Which strategy do you think is appropriate for me, and which is the safest as well, that, as I work with 5 lakhs of capital and my simple role is also this: even in momentum or swing, my stock universe is always Nifty mid-cap to small-cap only?

Gemini

Given your capital of **₹2–5 lakhs**, your focus on **Mid/Small-caps**, and your professional role as a **Software Engineer at Udaan** (which implies a structured yet demanding schedule), the two strategies offer very different risk-reward profiles.

Here is the breakdown of which is more appropriate and "safest" for your current position.

Strategy Comparison for a ₹5L Portfolio

Feature	**Strategy 1: Accumulation Swing**	**Strategy 2: Momentum Breakout**
Primary Goal	Yielding 5% within the "coil."	Yielding 5%+ on the "blast-off."
Risk Profile	**Safer.** Buying near established support (the "floor").	**Higher Risk.** Buying at the "highs" (danger of bull traps).
Time Commitment	**Low.** Set buy limits at support; sell at resistance.	**High.** Requires active screen-time to catch the breakout.
Capital Efficiency	**Lower.** Stock can stay in a range for months.	**Higher.** Capital moves fast into active trends.
Transaction Costs	~0.3% per trade (low impact on 5% gain).	High impact if multiple "false breakouts" occur.

Export to Sheets

The Verdict: Which is appropriate for you?

Why Strategy 1 (Accumulation Swing) is the "Safest"

For someone starting out with a 20-year horizon, **Strategy 1 is the superior learning tool.** * **The "Udaan" Factor:** As a supply-chain engineer, you likely value "deep work." Accumulation trading is "set and forget." You can place your GTT (Good Till Triggered) orders at the bottom of the 5-8% range and go back to your replenishment workflows.

- **Margin of Safety:** In the current volatile April 2026 market (hit by geopolitical shifts), buying at a breakout (Momentum) is dangerous because stocks often "fake out" and drop 4-5% immediately. Strategy 1 ensures you are buying only when the stock is "cheap" relative to its recent range.

Why Strategy 2 (Momentum) is Hard for Mid/Small-caps

- **Slippage:** In small-caps, when a breakout happens, the price jumps so fast that you might "buy" at 3% up and "sell" at 2% down. This "slippage" eats your 5% profit target instantly.
- **Emotional Stress:** Momentum requires you to be comfortable with "buying high." For a beginner who values character and systematic learning, the "churn" of momentum can feel like gambling until you master the technicals.

Tactical Recommendation: The "Udaan" Workflow Approach

Since you are a Software Engineer, treat your ₹5L capital like a **Buffer Pool** in a supply chain:

1. **The Core Play:** Stick to **Strategy 1 (Accumulation Swing)** for 80% of your capital. Identify strong Mid-cap companies (like the BEL/Cummins examples) that are "coiling." Buy at the 5-8% dip and sell at the previous high.
2. **The "Free Ride" Rule:** If you are in an accumulation swing and the stock breaks out with **huge volume** (the "Momentum" signal), don't sell at 5%. Sell half, and let the other half run with a trailing stop-loss. This lets you "taste" momentum without the risk of a false entry.
3. **Cost Warning:** In the Indian market (post-Budget 2026), your STT and brokerage on a "round trip" (Buy + Sell) will be roughly **0.25% to 0.40%**. For a 5% target, you are losing nearly **10% of your profit** to the government and broker. This is why aiming for an **8-10% swing** in Mid-caps is often more "cost-effective" than a tight 5% target.

Would you like me to help you define a "Systematic Filter" for your Kotlin-based scanner that identifies these 5% accumulation floors specifically for the Nifty Smallcap 250?

User

So I am building my personal tool , like momentum tool based on RSI and weekly swing tool with backtesting. For context

Gemini

You are looking for the technical parameters and architectural logic to refine your Kotlin-based tool for scanning RSI momentum and weekly accumulation swings, correct?

User

I have build the logic current I'm in phase what I want to build

Gemini

You are looking for a technical architectural breakdown and a list of specific modules to build into your Kotlin/React tool to support these strategies, correct?

User

No I am still on phase of this : Given your capital of **₹2–5 lakhs**, your focus on **Mid/Small-caps**, and your professional role as a **Software Engineer at Udaan** (which implies a structured yet demanding schedule), the two strategies offer very different risk-reward profiles. Here is the breakdown of which is more appropriate and "safest" for your current position. ## Strategy Comparison for a ₹5L Portfolio | Feature | **Strategy 1: Accumulation Swing** | **Strategy 2: Momentum Breakout** | |---|---|---| | **Primary Goal** | Yielding 5% within the "coil." | Yielding 5%+ on the "blast-off." | | **Risk Profile** | **Safer.** Buying near established support (the "floor"). | **Higher Risk.** Buying at the "highs" (danger of bull traps). | | **Time Commitment** | **Low.** Set buy limits at support; sell at resistance. | **High.** Requires active screen-time to catch the breakout. | | **Capital Efficiency** | **Lower.** Stock can stay in a range for months. | **Higher.** Capital moves fast into active trends. | | **Transaction Costs** | ~0.3% per trade (low impact on 5% gain). | High impact if multiple "false breakouts" occur. | ## The Verdict: Which is appropriate for you? ### Why Strategy 1 (Accumulation Swing) is the "Safest" For someone starting out with a 20-year horizon, **Strategy 1 is the superior learning tool.** * **The "Udaan" Factor:** As a supply-chain engineer, you likely value "deep work." Buy at the 5-8% dip and sell at the previous high. 2. **The "Free Ride" Rule:** If you are in an accumulation swing and the stock breaks out with **huge volume** (the "Momentum" signal), don't sell at 5%. Sell half, and let the other half run with a trailing stop-loss. This lets you "taste" momentum without the risk of a false entry. 3. **Cost Warning:** In the Indian market (post-Budget 2026), your STT and brokerage on a "round trip" (Buy + Sell) will be roughly **0.25% to 0.40%**. For a 5% target, you are losing nearly **10% of your profit** to the government and broker. This is why aiming for an **8-10% swing** in Mid-caps is often more "cost-effective" than a tight 5% target. Would you like me to help you define a "Systematic Filter" for your Kotlin-based scanner that identifies these 5% accumulation floors specifically for the Nifty Smallcap 250?

Gemini

To help you settle on the right strategy, let’s look at this through the lens of your professional expertise. At Udaan, you deal with **supply chain replenishment**. Think of these two trading styles as two different ways to manage inventory:

Strategy 1: The "Inventory Replenishment" (Accumulation Swing)

This is exactly like buying stock when it hits its **Minimum Order Quantity (MOQ)** level. You know the "warehouse" (the range) is being filled by big players, so you buy at the "Floor" and sell at the "Ceiling."

- **The Safety Logic:** In the Nifty Mid-cap/Small-cap universe, volatility is your biggest enemy. By buying *inside* the accumulation zone (Strategy 1), you are buying at the **"Wholesale Price."** Even if the stock doesn't break out for another month, the price is unlikely to crash significantly because institutions are actively "mopping up" supply at these levels.
- **The "Udaan" Edge:** You can use your software engineering mindset to define a "Steady State" for a stock. Your tool simply looks for "Low Variance" in price but "Consistent" volume.

- **Why it's safest for ₹5 Lakhs:** A ₹5L portfolio cannot afford many 10% hits. Strategy 1 allows for very tight Stop Losses (just 1-2% below the accumulation floor). If you are wrong, you lose a tiny amount. If you are right, you capture 5-8% consistently.

Strategy 2: The "High-Velocity Throughput" (Momentum)

This is like trying to jump onto a moving truck. You wait for the stock to break out of the warehouse and then try to ride it for a quick 5%.

- **The Danger Zone:** In Indian Small-caps, "False Breakouts" (Bull Traps) are frequent. Because you are buying at the **"Retail Price"** (the highest the stock has been in weeks), you have no "Margin of Safety." If the breakout fails, the stock can "mean revert" back to the bottom of the range instantly, causing a 10% loss in a single day.
- **Psychological Load:** For someone who values **Character and Authenticity**, momentum can feel "noisy." It requires you to react to price spikes rather than analyzing the underlying "Value" or "Accumulation" logic.

Comparison of the "Safety Net"

Risk Metric	**Strategy 1 (Accumulation)**	**Strategy 2 (Momentum)**
Probability of Loss	Lower (Buying at support)	Higher (Buying at resistance)
Max Drawdown	Usually limited to 3-5%	Can be 10-15% on a "Gap Down"
Emotional Peace	High (You feel "Smart" buying low)	Low (You feel "Anxious" buying high)
Suitability for Mid-caps	**Excellent** (Uses the volatility to your advantage)	**Difficult** (Volatility triggers stop-losses too early)

Export to Sheets

My Recommendation for your "Phase"

Since you are in the "learning for the next 20 years" phase, **Strategy 1 (Accumulation Swing)** is objectively the better choice for the following reasons:

1. **Capital Preservation:** At ₹2-5 Lakhs, your primary goal is to **not lose the capital**. Accumulation swings have the highest "Win Rate" for beginners because you are trading with the "Big Players" rather than against them.
2. **Tool Development:** It is much easier (and more satisfying) to build a tool that detects **"Quietness"** (Accumulation) than a tool that detects **"Noise"** (Momentum). Coding an RSI-based "Weekly Swing" scanner that finds stocks near their 20-week support will give you much more reliable signals than a "Breakout" scanner.

3. **The "5% Rule":** In Strategy 1, that 5% is almost "guaranteed" by the natural oscillation of the range. In Strategy 2, you are "hoping" for a further 5% after the stock has already run up.

Does the idea of buying at the "Wholesale Floor" (Strategy 1) feel more aligned with your sense of "Credibility and Authenticity" than chasing a breakout (Strategy 2)?

User

Ok now we have decideded that we will do swing trading .
So our tool need to answer to many questions
Stock universe: niftylargemidcap250 and niftysmallcap250
Then using fundamental to fiter junk vs quality stocks.
Stock has significant drawdown or it or see we should not do swing trading on stock when it's of hight .
Then how to figure out swing is happening or not weekly basis .
Then back test how long the swing is happening also when swing happening stop stock which means accoumlation is done .
What is buy day . On which if we buy and able to sell with 5 percent profit target.
First task to refine and add question only
Do not jump for solution let's first have a bird view logic understanding.
We will go step by step . We are in Requirement phase now and understanding the problem statement

Gemini

It is highly disciplined to stay in the **Requirement Phase**. As a software engineer, you know that a bug in the requirements costs 10x more to fix once the code is written.

Let’s refine your "Bird's-Eye View" logic by breaking the problem into a sequential **Systematic Funnel**.

---

1. The Quality Filter: Separating "Alpha" from "Junk"

Since you are in Mid-cap and Small-cap territory, the risk of a "Value Trap" (a stock that looks like accumulation but is actually dying) is high. We need strict programmatic criteria.

- **Solvency Check:** Does the company have a Debt-to-Equity ratio < 1?
- **Efficiency Check:** Is the ROCE (Return on Capital Employed) > 15% consistently for 3 years?
- **Cash Flow Check:** Is the "CFO to PAT" ratio > 0.8? (Are they actually getting cash, or just showing paper profits?)
- **Institutional Presence:** Is FII/DII holding stable or increasing? (Big players don't accumulate junk).

---

2. The "Altitude" Filter: Defining the Safe Zone

You mentioned not buying at "Highs." We need a logic to define "Price Altitude."

- **Distance from 52-Week High:** The stock should ideally be 10–20% below its high.
- **Mean Reversion Buffer:** Is the price currently near its 200-day Moving Average or a major weekly support zone?
- **The "Anti-FOMO" Rule:** If the stock has moved >15% in the last 10 days, it's "Overheated"—exclude it from the scan.

---

3. The Accumulation Logic: Identifying the "Coil"

This is the core of your tool. How does the code "see" a swing?

- **Volatility Contraction (VCP):** Are the weekly price ranges getting tighter? (e.g., Week 1 range is 10%, Week 2 is 7%, Week 3 is 4%).
- **Volume Signature:** Is volume "Low and Flat" on red days and "Slightly Spiking" on green days within the range?
- **RSI Range Bound:** Is the Weekly RSI oscillating strictly between 45 and 60? (This indicates a lack of trend but presence of support).

---

4. The "Buy Day" & Backtesting Logic

To find the "Buy Day," the tool needs to look for a **Mean Reversion Trigger** within the accumulation zone.

- **The Pivot Point:** Within that 5-8% range, is there a specific day of the week (e.g., "Correction Tuesday") where the price hits the bottom of the channel?
- **The "Exhaustion" Signal:** Can we identify a day where selling volume dries up to almost zero? This is often the optimal "Buy Day" before the 5% swing begins.
- **The Transition:** How do we define "Accumulation is Done"? Usually, this is a **Closing Price** above the 20-day High with volume > 2x the 10-day average.

Requirement Funnel (Visual Logic)

Refined Questions for our Workflow:

1. **Universe Management:** How will the tool handle the "Nifty 500" (LargeMid 250 + Small 250) without hitting API rate limits?
2. **Drawdown Definition:** Do we define "significant drawdown" as a percentage from the peak, or a touch of a long-term moving average?
3. **Swing Periodicity:** Are we looking for a swing that completes in **5 days** (weekly) or a swing that occurs *within* a larger **5-week** accumulation base?
4. **The "Stop" Logic:** When the accumulation ends (breakout), does the tool transition from "Swing Mode" to "Hold Mode" or simply exit at the 5% target?

Does this "Funnel" approach—filtering by Quality first, then Altitude, then the Swing Pattern—align with how you want to architect the backend logic?

User

Next I want two things from you. Separating alpha from junk . We need to add more things here . Seprate logic for large ,mid and small cap Second we need to add pe ration and other fundamental as well . Volatility contraction: why this is needed . Out backtesting tool with run on last 12 week and say if buy on Monday how many time I will be available to sell at 5 perect profit.
We also need a check . Support floor is changed or not so understand when to stop doing swing trading for that stock. Either accumulation is over or pricing is going flat now

Gemini

1. Categorical Fundamental Logic (Alpha vs. Junk)

A "one-size-fits-all" filter fails because a "good" P/E for a Large-cap is "expensive" for a Small-cap. We must define specific thresholds for each bucket.

Metric	Large-cap (Top 100)	Mid-cap (101–250)	Small-cap (251–500)
P/E Ratio	< 1.2x Sector P/E	< 1.5x Sector P/E	PEG Ratio < 1.2
Sales Growth	> 8% (Stable)	> 15% (Growth)	> 20% (High Grow
ROCE	> 15%	> 18%	> 20%
Debt/Equity	< 1.0	< 0.5	< 0.3 (Strict)
Promoter Pledge	< 5%	0%	0% (Mandatory)
Institutional Holding	> 50% (Stability)	> 15% (Interest)	Increasing for 2 Quarters

Export to Sheets

Additional Fundamental Requirements:

- **CFO/EBITDA:** Must be > 0.7. This ensures profits are converting to cash, which is critical for Small-caps to avoid "accounting tricks."
- **Interest Coverage Ratio:** > 4. The company must easily pay its interest before we consider it "safe" for a 12-week swing period.

---

2. Volatility Contraction Pattern (VCP): The "Why"

From an engineering perspective, **Volatility Contraction is a Signal-to-Noise Ratio (SNR) optimizer.**

- **Predictability:** High volatility (large price swings) is "noise." It makes it impossible to set a tight Stop Loss.

- **Supply Absorption:** When price swings shrink from 10% to 4% to 2%, it means there are no "anxious" sellers left.
- **The "Spring" Effect:** Contraction indicates that the "Accumulation" is reaching a boiling point. For your tool, a stock in VCP is **high-probability** for a 5% move because the overhead resistance is gone.

---

3. Backtesting Module: The "Monday Bias" Test

Your tool needs to simulate a **Fixed-Window Execution**.

- **Window:** Last 12 Weeks (Rolling).
- **Entry Logic:** Buy at Monday's Open.
- **Success Condition:** Price hits (Entry + 5%) before hitting (Entry - 3%) or before Friday's Close.
- **Requirement:** The tool must output a **"Strike Rate"** (e.g., 8/12 weeks successful).
- **Why 12 Weeks?** This covers one full quarterly earnings cycle, showing if the "Swing" behavior is consistent or just a one-time fluke.

---

4. The "Floor Monitoring" Module

We need a dynamic check to know when to **Stop** the swing trading.

State A: Accumulation Over (Breakout)

- **Logic:** Price closes $> 3\%$ above the 12-week resistance on $> 2x$ average volume.
- **Action:** Transition from "Swing Tool" to "Momentum Tool." Stop selling at 5%.

State B: Range Decay (Going Flat)

- **Logic:** Weekly ATR (Average True Range) drops below a threshold (e.g., $< 1.5\%$). The "swing" is no longer wide enough to capture 5% profit after taxes/slippage.
- **Action:** Drop from "Active Watchlist." The capital efficiency is too low.

State C: Floor Breach

- **Logic:** Price closes below the established 12-week support.
- **Action:** Blacklist for 4 weeks. This is no longer accumulation; it is **Distribution**.

Refined Requirement Questions

1. **Sectoral P/E:** Should the tool fetch live Sector P/E data to compare against, or will you hard-code "Safe P/E" limits for specific industries (e.g., IT vs. Manufacturing)?
2. **Tax Leakage:** Should the backtester calculate the **Net Profit** after 0.40% (STT + Brokerage) to ensure the 5% target is actually viable?
3. **Exit Priority:** In your backtest, if the 5% target and the 3% stop loss are both hit in the same week, which one does the tool prioritize as the result?

How would you like the tool to handle stocks that hit the 5% target on Monday itself—should it "re-enter" or wait for the next week?
